1. Introduction

In many developing countries, access to conventional medicine remains limited to large cities. The difficulties of travel, shortage of qualified personnel, high cost of benefits and conventional medicines and socioeconomic factors, leave a large part of the population no other choices, than to resort to traditional medicine for common disease treatment [1]. Complementary and alternative medicine are commonly used to treat or prevent chronic diseases and to improve the quality of life. In Africa, more than 80% of the population uses traditional medicine and medicinal plants for their primary health care [2]. Some of these medicinal herbs have great potential and have been shown to be very beneficial in the treatment of wounds, promoting the healing rate of wounds with minimal pain, discomfort and scarring in the patients [3]. Faced with these problems, it is essential to find new effective and broad-spectrum substances that can fight against bacterial infections and attenuate or delay the oxidative process. One of the strategies for this research is to explore the plants used in traditional medicine. Many studies have shown that plants have antioxidant properties largely due to their phenolic compounds [4]. Phenolic compounds play an important role in human health because of their various pharmacological activities as anti-inflammatory, antiallergic, antimicrobial, antiviral, anticancer, cardioprotective and vasodilatory [5,6]. It is in this context, that in the framework of this study a species of the genus Albizia, widely used in the traditional pharmacopoeia to treat certain venereal diseases and for these antioxidant properties was studied [7]. The plants of the genus Albizia belong to the Fabaceae family and are widespread. This genus comprises about 120 species and is found in all tropical regions. *Albizia ferruginea* is a large deciduous tree up to 45-50 m tall; bole branchless up to 22 to 30 m tall, straight and cylindrical, up to 100 to 130 cm in diameter [8]. *Albizia ferruginea* is a medicinal plant widely used in Africa [9]. The bark is used in traditional medicine to treat dysentery, bronchial infections and pain caused by fever. In external application, it is used to treat wounds, pimples and other skin infections. In central Cameroon, natives use leaves maceration as a purgative in children to treat intestinal disorders [8,9]. Very few phytochemical studies have been carried out on *Albizia ferruginea*, the work carried out by Kamga in 2014 only has led to the isolation of a Flavonoid [10]. However, some secondary metabolites isolated from other species are terpenoids, saponins, steroids and tannins [9]. Given the fact that very few phytochemical studies have been carried out on this plant and the use of this plant in traditional medicine, all these elements motivated our study to compare these traditional uses with scientific data. Thus, the general objective of this study is to evaluate the antioxidant properties of secondary metabolites isolated from the roots of *Albizia ferruginea* (Fabaceae).

2. Experimental Methods

2.1 General Experimental Technique

The powder material was macerated in CH₃C₂=OH (1:1) in tightly sealed 2 L can. A MARQUETTA NM-300P electronic scale weighed the raw extract and the different masses of the fractions. Flash chromatography was performed using a Velp Scientifica vacuum cleaner, a Buchner and a vacuum flask. A Büchi brand Heidolph WB 200 rotary evaporator was used for concentration of the mixture to dryness and not separation. Column chromatographs were carried out in a column 3 cm in diameter and 60 cm long and a small column 2 cm in diameter and 50 cm in length. Stationary phase Kieselgel 60 type silica (0.04–0.063 mm) was used. The HCl and 1% NMR spectra were recorded with a Bruker DRX-600 at 600 and 150 MHz, respectively. This was done at the laboratory of the Institute of Environmental Research of the Faculty of Chemistry, Dortmund University of Technological, Germany.

2.2 Plant Material

The roots of *Albizia ferruginea* were harvested in the Centre region of Cameroon, Moundi Division, Yaounde III subdivision, Etoa village along Ngoumou old road about 3 km from the Barrier crossroads in January.
2.3 Extraction and Isolation

The roots of *Albizia foggina* were dried, crushed and a (3.5 kg) powder was obtained. This powder was macerated in 2 L of *ChCl*–MeOH (1:1) for 72 h. The filtrate obtained was evaporated to dryness using a rotary evaporator under reduced pressure (200 g) of crude extract were obtained. One hundred and fifty grams (150 g) of this crude extract was cold-extracted on (150 g) of silica gel (SiO2). (0.065–0.200 mm) and the silica gel was washed with (170 g) of silica as stationary phase to subjected flash chromatography. The column was eluted with a gradient of hexane, hexane/ethyl acetate, ethyl acetate, ethyl acetate/methanol then. After elution, 350 vials of about 400 ml each were collected. Three hundred and fifty 350 vials were pooled into 5 major fractions A (70 g), B (5 g), C (35 g), D (15 g), and E (25 g) were collected, concentrated and grouped based on similar TLC profiles.

2.4 Purification of the Different Fractions

2.4.1 Chromatography of Fraction A

Fraction A (70 g) was fixed on (80 g) of silica gel and then column chromatography done with (100 g) of silica gel (0.063–0.200 mm) as stationary phase. Elution of this was done with hexane and hexane/ethyl acetate mixture by gradient of increasing polarity; We thus collected 150 vials grouped into 4 major fractions (A1, A2, A3, A4) per their TLC analysis.

Fraction A2 led to the isolation of (22E, 24S)-Stigmasta-5,22,25-trien-3β-ol (1) (15 mg) in the hexane/ethyl acetate system 20 % and soluble in methylene chloride.

Fraction A3 led to the isolation of 3’,4’,5,7-tetrahydroxyflavone (luteolin) (2) (20 mg) in the hexane/ethyl acetate 30% system and soluble in methanol.

Fraction A4 led to the isolation of Quercetin (3) (10 mg) in pure ethyl acetate and soluble in methanol.

2.4.2 Chromatography of Fraction C

Chromatography of fraction C on a silica gel column using *ChCl*–acetone (95:5) as eluent provided a fraction which was further purified by column chromatography with *ChCl*–acetone (90:1) and then (+)- to give Kaempferol-7-0-β-D-glucoside (4) (12 mg).

2.4.3 Chromatography of Fraction D

Fraction D was chromatographed on a column of silica gel, eluting with Hexane/ethyl acetate at increasing polarity. The fraction obtained with the mixture (65:35) was recrystallized from methylene chloride to give the aliphatic acid (5) (23 mg).

2.4.4 Chromatography of Fraction E

Fraction E was chromatographed on a column of silica gel eluting with *ChCl*–AcOEt with increasing polarity. The fraction obtained with the mixture (95:5) was further purified by column chromatography using *ChCl*–AcOEt as eluent and gave β-sitosterol palmitate (6) (10 mg).

2.5. Physical State and Spectral Data of Compounds (1–6)

(22E, 24S)-Stigmasta-5,22,25-trien-3β-ol (1) (15 mg), Calculated mass of C21H29O, m/z = 410.20 g/mol, white needle; *1H NMR* (600 MHz, CDCl3): δ 6.68 (1H, d, J = 7.6 Hz, H-2), 1.00 (3H, d, J = 6.4 Hz, H-21), 1.68 (1H, s, H-27), 3.53 (1H, m, H-3), 4.70 (2H, bs, H-26), 2.57 (1H, dd, J = 15.6, 7.2 Hz, H-23), 5.24 (1H, dd, J = 15.6, 7.6 Hz, H-22), 5.34 (1H, d, J = 5.6 Hz, H-6).

- **1C NMR** (150 MHz, CDCl3) 6 ppm: 37.24 (C-1), 148.60 (C-25) 140.74 (C-5), 137.18 (C-22), 130.02 (C-23), 121.67 (C-6), 109.50 (C-26), 71.79 (C-3), 56.83 (C-14), 55.87 (C-17), 51.98 (C-19), 50.14 (C-9), 42.49 (C-13), 42.24 (C-4), 40.17 (C-21), 39.66 (C-12), 36.49 (C-10), 31.86 (C-7), 31.65 (C-2), 28.86 (C-16).
- 3’, 4’, 5, 7-tetrahydroxyflavone (luteolin) (2) (20 mg): yellow amorphous powder; mp: 325 °C; Rf value of 0.40 in solvent IV, UV Abs (MeOH) 254, 269, 300 (α = 0.96; 0.90; 0.88), 343 (absorption maximum), 393 (absorption maximum), 421, 274, 355, (MeOH + NaOAc) 269, 393 (MeOH + NaOAc + H2O), 264; IR (KBr cm-1): 3420 (OH), 2948 and 2933 (CH3) 1609 (C=O), 1595 (C=O), 1261, 1168, 1120 (C=O), 830, 755, 688; EI-MS m/z: 286 [M+H]+, 258, 228, 153, 135, 134, 96.
- The *1H NMR* (200 MHz, CDCl3): δ 6.62 (1H, s, H-3), 6.18 (1H, d, J = 17.5 Hz, H-6), 6.42 (1H, d, J = 7.5 Hz, H-8), 7.36 (1H, d, J = 2.5 Hz, H-5), 6.98 (1H, d, J = 8.6 Hz, H-5) and 7.34 (1H, d, J = 8.6 Hz, H-5).

**2.6 Method of Evaluating Antioxidant Power**

The antioxidant activity of the compounds will be determined quantitatively and qualitatively by DPPH and FRAP (Ferric Reducing Antioxidant Power) methods. The DPPH method is based on the ability of an antioxidant in reducing 2,2-diphenyl-1-picrylhydrazyl (DPPH) to a yellow compound diphenyl picryl-hydrazine.

2.6.1 Quantitative Test of the Reduction of Free Radical DPPH

2.6.1.1 Principle

The effect of the compounds on the stable DPPH*+* was determined by the Molyneux method (Fig. 1) [11]. The method is based on the degradation of the DPPH*+. In the presence of an antioxidant capable of yielding a single electron, the purple DPPH*+* will be stabilized in DPPH and thus decolorization of the solution will occur. The degradation of the radical measured by spectrophotometry at 517 nm is proportional to the concentration of antioxidant (11).

**Fig. 1** DPPH Free radical conversion DPPH-H by antioxidant compounds

![DPPH](https://via.placeholder.com/150)

2.6.1.2 Method

In various test tubes, we introduced 3000 µL of a µL of test compounds (75 mg/µL, 100 mg/µL, 150 mg/µL and 300 mg/µL) followed by the addition of 300 µL of a 0.1 M ethanol solution of DPPH and 100 µL of a 0.6 M solution of H2SO4. After 15 minutes of mixing, the absorbance of the solution was measured at 517 nm using a spectrophotometer.
by 1000 µL of the DPPH+ methanol solution (0.1 mM). After vortexing, the mixture was left in the dark for 30 min and the optical density was measured at 517 nm. The negative control was prepared solely based on the compound-free DPPH solution and the positive control being represented by the standard antioxidant solution (vitamin C) whose absorbance was measured under the same conditions as the test sample. The antioxidant activity is estimated as a percentage inhibition or percentage of antioxidant activity, according to the following formula,

\[
\% \text{Inhibition of the radical DPPH} = \left( \frac{\text{Abs DPPH} - \text{Abs Compounds}}{\text{Abs DPPH}} \right) \times 100
\]

where Abs DPPH is the absorbance of the hydroethanol solution of DPPH+ and Abs compounds, compound at the wavelength of 517 nm. The IC values (concentration of compounds required to trap 50% of the free radicals) were then calculated from the regression equations obtained for different concentrations of the different compounds. Table 1 shows the procedure for the determination of the free radical potential by the DPPH method.

2.6.2 Determination of Antioxidant Potential by Ferric Reducing Antioxidant Power (FRAP)

2.6.2.1 Principle

FRAP was determined according to the method of Benzie and Strain [12]. This method measures the ability of the samples to reduce iron, in ferric form (Fe³⁺) to the ferrous form (Fe²⁺) at a low pH (3.6). An intense blue color is formed when the ferric tripyridyltriazine (TPTZ) complex is reduced to ferrous tripyridyltriazine and the absorbance is measured at 593 nm, the higher the absorbance, the higher the reduction power [12].

2.6.2.2 Method

In test tubes containing 75 µL of sample solution (100 µg/mL) 100 µL of FRAP reagent was added. Absorbance was then read spectrophotometer at 593 nm after 12 min incubation. We have prepared under the same conditions a control with distilled water in place of the solution of the compounds. The quantification was carried out according to a standard range established under the same conditions with ascorbic acid (0 to 80 µg/mL). The results will be expressed in equivalent mg of ascorbic acid/g dry matter. Table 2 shows the procedure for determining the antioxidant potential of the compounds by the FRAP method.

Ascorbic acid was used as a positive control and the results were expressed in equivalent mg of ascorbic acid per gram dry matter (mg AAE/g MS) using the following regression equation: y = 0.0019x + 0.4 (R²=0.925).

3. Results and Discussion

The roots of *Albizia ferruginea* were cut, dried and crushed; (3.5 kg) of powder thus obtained were macerated in 20 L of CHCl₃-MeOH 1:1 for 72 hours. The filtrate was concentrated on a rotary evaporator, which made it possible to obtain 200 g of crude extract. This extract was subjected to a Phytochemical Screening and fractionation to evaluate the antioxidant activities, then to isolate the secondary metabolites found in these fractions.

Extracts of *Albizia ferruginea* were fractionated by silica gel column chromatography to give six compounds (1-6) (Fig. 2).

**Fig. 2 Structure of compounds 1 to 6 isolated from *Albizia ferruginea***

The compound (1) was obtained in the form of white powder sheet in the hexane ethyl acetate 20% system, it is soluble in ethyl acetate and crystallized in methanol. Its molecular formula is C₂₀H₂₄O₇ and its calculating mass is m/z 342.1400. Its IR spectra showed in the weak fields: A broad multiple at 3,560.325 cm⁻¹ attributable to the hydroxylated carbon, A broad doublet of an ethylene proton at δH = 3.53 ppm and two doublets doubled at δH = 5.24; 5.17 ppm. Signals at δH = 3.52; 3.52; 5.24 and 5.17 attributable to protons H₅, H₆ and H₇. Signals of three singlet characteristic of angular methyls at δH=0.69 ppm (H₃), 1.01 ppm (H₄); (H₅); 1.65 ppm (H₆). Finally, a triplet at δH = 0.85 ppm attributable to H₂ to H₅. These data clearly show that (1) has a stigmasterol-like backbone [13]. The ¹H NMR spectrum, completely decoupled, reveals the presence of 29 carbon signals, among which six ethylenic carbons at δC = 140.90 ppm; 12.84 ppm; 137.35 ppm; 130.17 ppm; 148.78 ppm and 109.66 ppm attributable respectively to C₃, C₅, C₆, C₇, C₈, C₉ and C₁₀. A signal characteristic of a hydroxylated carbon at δC = 71.96 ppm attributable to C₁₀. To finish a set of carbon sp³ at δC between 56.99 to 12.21 ppm. On the basis of these data and in comparison, with the data of the literature, the compound (1) has been given the following name (22E, 24S)-stigmasta-5,22,25-trien-3β-ol [14,15], isolated from *Albizia ferruginea* for the first time.

The IR spectrum of the compound (2) showed a hydroxyl absorption band at 3420 cm⁻¹ and a carbonyl group band at 1609 cm⁻¹. Compound 2 was recognized as a Flavone compound based on its UV absorption maxima at 349 nm (band I) and 254 nm (band II) [16]. The EI-MS spectrum had a molecular ion at m/z = 286 [M⁺] with fragments at m/z 258 [M⁻100], 153 [benzyl portion of ring A] and 135 [acetyl group of ring B]. Its ¹H NMR spectrum showed the signals of the ABX ring B spin system at δH 7.36 (1H, d, J = 2.1Hz), 7.34 (1H, dd, J = 4.1, 6.2Hz) and 6.98 (1H, d, J = 8.6 Hz) for H-2', H-6' and H-5, respectively. He also showed a singlet signal at δH 6.52 for H-3. Two protons were at δH 6.42 (1H, d, J = 1.7 Hz) and 6.18 (1H, d, J = 1.7 Hz) for H-8 and H-6, respectively. On its ¹³C NMR, the carbonyl signal is observed at δC 182.7 (C-7) and the signal C-3 at δC 103.1. Oxygen containing the carbons showed downward signals at δC 165.0 (C-7), 164.7 (C-9), 160.0 (C-2), 158.5 (C-1), 149.6 (C-4) and 145.7 (C-3) for carbon atoms carrying oxygen. By comparing the UV, IR, MS, and ¹H and ¹³C NMR spectra of compound 2 in the literature [16], compound 2 was identified as 3',4',5,7-tetrahydroxyflavone (luteolin), already isolated from *Albizia lebbeck* [17], but isolated for the first time from *Albizia ferruginea*.

The compound (3) is obtained with pure acetate and is soluble in methanol. On its IR spectrum, we observe the vibration bands at 3214 [OH], 2905 [C-H], 1732 [C=O], 1657 [C=O], 1615 [C=O], 1504, 1349 and 1230 cm⁻¹. ¹H NMR CDCl₃ (500 ppm) 6.17 (1H, d, J = 1.8Hz, H-6), 6.38 (1H, d, J = 1.8Hz, H-8); 8H 6.89 (2H, d, J = 9.2 Hz, H-2', 6'); 8H 8.08 (2H, d, J = 8.8 Hz, H-3', 5'). ¹³C NMR (CDCl₃) 89.44 (C-9), 99.3 (C-6), 104.5 (C-10), 116.3 (C-3'), 123.7 (C-1'), 130.7 (C-2'), 137.2 (C-3), 140.8 (C-9), 158.2 (C-8), 165.0 (C-1'), 1625.7 (C-7), 1656.4 (C-4') and 1774.4 (C-4). On its ¹H NMR spectrum, 5 aromatic signals are observed. The aromatic proton doublets at 6.25 and 6.50 ppm (J = 1.8 Hz) were due to the protons meta-coupling of a 5,7-substituted ring A for the H-6 and H-8 protons. Respectively, while the signals at 6.98 (d, J = 8.4 Hz, 1H), at 7.66 (dd, J = 1.8, 8.4 Hz, 1H) and at 7.79 (d, J = 1.8 Hz, 1H) were assigned to the H-5', H-6' and H-2' protons, showing an ABX coupling system of 3', 4'-substituted.
B-ring flavanol. On the basis of these data and in comparison, with literature data, compound 3 has been identified with quercetin (3) [18-20].

Compound 4 showed a peak at m/z = 487.0844 in HR ESI-MS, corresponding to a molecular formula of C_{23}H_{28}O_{12}Na, corroborated by 1^\text{H} NMR data. The APCI-MS spectrum of 4 showed peaks at m/z = 301 (loss of 162), suggesting the presence of a hexose linkage to an aglycone moiety. The configuration of the sugar moiety was determined to be the basis of the anomeric proton coupling constant (110.200 = 7.6 Hz). In addition, the anomeric proton had a correlation in the HMBC spectrum with 5 C 163.7 (C-7). These physical and spectroscopic data compared to those described in the literature have identified compound 4 as Kaempferol-7-

Of the compounds, we have distinguished the following characteristic peaks in the H NMR spectrum: signals at δ 1H 5.35 integrating 1H. Characteristic of the vinylic proton H-1 (δH 5.18 (1H, m) and at δH 5.06 ppm) integrating for 1H. Each and a pair of signals characterizing a carbonyl group, a broad and intense peak between δC 4.60 ppm (dd, J = 2.0 Hz) and a methyl (δH 3.61, ddd, J = 13.3, 9.6-4.6 Hz). The chemical shift of carbon C-2 (δC 70.0) confirms the presence of a hydroxyl group in position 2. The 1^\text{H} APT NMR spectrum of compound 5 reveals the presence of 30 carbons from which we can distinguish the following characteristic features: A signal resonant at δC 101.0 ppm indicating the presence of a free hydroxyl function. In the molecular ion of the compound, correlations between carbon 1 and carbons H-16, H-18, suggest that the carboxyl is placed in position 28. A carbon mass between 14-15 ppm attributable to CH2, CH and C quaternary. Two oxygenated carbons at δ 84.7 and 70.0 ppm. The two ethylenic carbons detected, including a quaternary carbon located at 152.2 and a methylene carbon 12 (10.5 ppm). By means of the analysis of the direct hetero-nuclear correlations 1^\text{H}-1^\text{H} observed on the J-modulated HSQC spectrum of 5 combined with the 1^\text{H} APT spectrum, we can count 7 quaternary carbons, 7 methines, 10 methylenes and 6 methyls for the compound 5. From the protons identified on the 1^\text{H} NMR spectrum, the corresponding carbons C-1 (δC 48.6), C-2 (δC 69.9) and C-3 (δC 84.5) of ring A; C-11 are assigned (δ 104.9, C-24 a ring C (δ 50.57), C-19 (δ 48.53), C-21 (δ 53.05) and C-22 (δ 37.1) of ring E. This analysis also makes it possible to identify the degree of substitution of the double bond deduced by the fact that the two ethylenic protons are carried by the same carbon (110.5 ppm) which confirms the presence of an isopropenyl exo-cyclic double bond (Δ2). The correlations observed between the protons H-18 (δH 1.66) and the carbons C-13, C-14, C-17, the quaternary carbon of the isopropenyl group (δC 150.2) and the carbonyl at 181.2 ppm allow to place unambiguously the isopropenyl group in position C-19 and the carbonyl in position 28 as well as in the lupane skeleton. The axial orientation of proton H-3 and axial proton H-2 is established from the values of the coupling constant between H-2 and H-3 in the medium greater than 9 Hz. The combination of all these physical and spectroscopic data compared to those described in the literature made it possible to identify the compound 5 to Alphitolic acid [23,24].

Compound 6 was obtained in the form of a white powder soluble in ethyl acetate. The analysis of its 1^\text{H} NMR spectrum shows in the weak fields a broad triplet integrating 1H at 5.35 ppm, two doublets of low intensity, one at 5.18 and the other at 5.06 ppm integrating for 1H. Each and a multiplet integrating 1H at 3.53 ppm. In strong fields, there is a large and intense peak between 1.25 and 1.29 ppm, integrating 20H and a peak characteristic of a terminal methyl at 0.91 ppm integrating 3H. On its 1^\text{H} NMR spectrum, olefinic carbons are observed at δC 140.76, 121.76, 138.54 and 139.71 ppm, oxygenated carbon at δC 178.38 ppm, a signal characterizing a carbonyl group, a broad and intense peak between 29.27 and 29.73 ppm and a signal 14.14 ppm. The peaks observed at δC 5.18 (1H, m) and at δH 5.06 (1H, m) are attributable respectively to the signals of the H-22 and H-23 protons of stigmastanol. In this case stigmastanol. This is confirmed on the HSQC spectrum by signals at δC 121.76 (C-6) and 140.76 (C-5) ppm. Similarly, on the 1^\text{H} NMR spectrum, the multiplet observed at δC 3.53 (1H) corresponding to a proton carried by an oxygenated carbon (C-3), characteristic of the H-3 proton steroidal derivatives. In addition, the peak observed at δH 1.70 ppm is attributable to C-17, which characterizes the carbonyl group bonded to the oxygen at position 3 of the sterol. The presence of a linear chain is explained by the presence of a peak set between 29.27 and 29.73 ppm attributable to C-4’ to C-13’ carbons and a terminal methyl group [25]. The analysis of its HSQC spectrum allows for the attribution of some carbon protons. Thus, in strong fields, between δC 6.07 and δH 1.02 ppm, there are several methyl groups that can be observed at δC 6.08 (3H, s, Me-18); 0.84 (3H, s, Me-29); 0.88 (3H, d, Me-26); 0.86 (3H, s, Me-27); 1.01 (3H, s, Me-19); 0.96 (3H, s, Me-21). On its HMBC spectrum, the correlation between the proton H-6 and the carbons C-4, C-10 and C-7, also the correlations between the proton H-4 and the carbons C-1, C-5, C-2, C-3 and C-6 is observed. We also note the correlations of proton H-18 and carbons C-12, C-13 and C-17. Moreover, correlations between the H-25 proton and the C-24 carbon are also observed. Based on these data, and in comparison, with the data of the literature, compound 6 has been identified as β-sitosterol palmitate of empirical formula C_{36}H_{60}O_{2} [25], which is isolated from Albizia ferruginea for the first time.

3.2 Evaluation of Antioxidant Power

The antioxidant capacity of the compounds is largely dependent on the composition of these compounds as well as the handling conditions of the in vitro tests. To determine the antioxidant activity of the compounds, we used qualitative and quantitative tests of the DPPH method and the FRAP method.

3.3 Determination of Antioxidant Properties by Trapping the Radical DPPH

Chromatograms of the residual and total aqueous ethyl alcohol extracts were revealed by the metathetical solution of 0.02% 1,1-diphenyl-2-picrylhydrazyl. The appearance of yellow-white spots on a purple background made it possible to demonstrate the presence of anti-radical compounds in the extracts tested.

3.3.2 Quantitative Test

The antiradical activity was evaluated only on compounds whose chromatogram showed the appearance of yellow-white spots on a purple background. The antiradical activity of these compounds and vitamin C vis-à-vis the DPPH radical was evaluated spectrophotometrically at a wavelength of 517 nm, following the reduction of this radical which is accompanied by its change from the purple color to yellow color. The representation of the antiradical activity as a function of the concentration shows that the compounds have antiradical activities. In addition, the growth of these activities in concentration dependent for each of the compounds tested. We also note that the antiradical activities of these compounds are significantly different (p<0.05) and are lower than those of vitamin C. However, at the 75 µg/mL dose the entrapment percentage of compound 5 is higher, at doses of 100 and 300 µg/mL compound 6 is the highest and finally at the dose of 150 µg/mL compound 1 which is the highest (Fig. 3). Table 3 evaluates the trapping capacity of the DPPH radical of the various Albizia ferruginea compounds.

![Fig. 3 Trapping capacity of the DPPH radical of the different compounds of Albizia ferruginea](https://example.com/fig3)

The antioxidant activity of the various compounds was determined using DPPH, 1,1-diphenyl-2-picrylhydrazyl, the effective concentration of compounds that traps 50% of free radicals. The IC_{50} and the antioxidant activity of the compounds tested are inversely proportional. The different optical densities made it possible to plot for each compound, the IC_{50} curve as a function of the concentrations of the compounds, which means the existence of a proportional relationship between the percentage of reduction of the free radical and the concentration of the compounds in the medium reaction. The plot of the IC_{50} histogram curve of the compounds is shown in Fig. 4. The IC_{50} values of the different compounds are shown in the Table 4.

https://doi.org/10.38099/jacs.212.19050301

These values make it possible to classify the strength of antioxidant activity due to the presence of many hydroxides that can react with free radicals [27]. The ability of compounds to trap free radicals depends on many parameters; the dose, structure, substituents and degree of polymerization of the molecule. Antiradical activity is very important because of the deleterious role of free radicals in the food and biological systems [27]. The DPPH radical method used in the present study is a common procedure in which the antioxidant activity of the sample studied is estimated by the degree of discoloration of the DPPH solution. This violet chromogen is easy to use, has high sensitivity, allows rapid analysis and the quantification of the antioxidant activity of the sample [27].

From the above histogram, we first notice that all our compounds have activities less important than the reference substance, ascorbic acid. Compounds (1) and (2) isolated from the roots of *Albizia ferruginea* show great activity. The antioxidant activity can therefore be classified within these compounds in descending order of activity: Ascorbic acid > compound (2) > compound (1) > compounds (3) and (4) can be classified in descending order of the anti-radical power, as follows: Ascorbic acid > compound (3) > compound (4) > compounds (5) and (6) can be classified in descending order of the anti-radical power, as follows: Ascorbic acid > compound (5) > compound (6) We observe these results in that whatever the solvent, the isolated compounds of *Albizia ferruginea* have a high activity.

Vitamin C

These results are in agreement with the work carried out in 2014 by Kamga and his collaborators who isolated a new flavone with antioxidant activity and 3 saponins in this plant [10]. According to a study conducted in 2007 by Sokol-letowska [26], some of these secondary metabolites like phenolic compounds (flavonoids and tannins) have an important antioxidant activity due to the presence of many hydroxides that can react with free radicals [27]. The ability of compounds to trap free radicals depends on many parameters; the dose, structure, substituents and degree of polymerization of the molecule. Antiradical activity is very important because of the deleterious role of free radicals in the food and biological systems [27]. The DPPH radical method used in the present study is a common procedure in which the antioxidant activity of the sample studied is estimated by the degree of discoloration of the DPPH solution. This violet chromogen is easy to use, has high sensitivity, allows rapid analysis of the antioxidant activity of a large number of samples and gives reproducible results [27]. The qualitative test of the DPPH radical reduction method performed on the compounds showed numerous antiradical stains on the chromatographic profiles of compounds 1 and 2. While the quantitative evaluation of the free radical scavenging activity of DPPH has confirmed that the compounds have an antiradical activity. Nevertheless, the trapping capacity of these compounds remains lower compared to that of vitamin C (IC_{50}=7.87 mg/mL). According to Souri's classification [26], compound 4 has a high potential for antiradical activity (IC_{50}=20 mg/mL). Compounds 1 and 5 have a potential for moderate antiradical activity (20<IC_{50}<75 mg/mL), compounds 2 and 3 have a low potential (IC_{50}> 75 mg/mL). The antiradical activity of these compounds can be attributed to the presence of phenolic compounds found in phytochemical analysis because phenolic compounds have been shown to have the ability to yield hydrogen atoms generally associated with the presence of reducing agents [29]. The action of these antioxidants is

4.3.4 Determination of Total Antioxidant Capacity by FRAP Method

According to the calibration curve (Fig. 5) and the regression line, the contents recorded in Table 5 are observed. We observe a reduction of ferric tripyridyltriazine (TPTZ) complex to ferrous tripyridyltriazine when a reducing agent such as an antioxidant substance is present in the compounds. The results of this method are contained in Table 5.

For compounds 1 and 2 the FRAP values vary respectively between 543.85±16.91 mg EAA/g MS and 154.91±143.68 mg EAA/g MS. Then for compounds 3 and 4 the values vary between 689.47±46.77 mg EAA/g MS and 2556.14±44.76 mg EAA/g MS and finally for compounds 5 and 6 they vary between 2666.67±270.08 mg EAA/g MS and 4333.33±511.18 mg EAA/g MS. These values make it possible to classify the strength of antioxidant activity according to the isolated compounds of *Albizia ferruginea* in the following descending order: compound 1 has an activity higher than the compound 2, by contrast compound 3 has an activity higher than compound 4 and finally compound 5 has an activity greater than compound 6.

This test shows that the roots of *Albizia ferruginea* are the part of the plant that has the highest antioxidant capacity for this method in the different solvents. Compound 6 exhibited the highest antioxidant capacity (4333.33±511.18 mg EAA/g MS). In addition, a statistically significant variation of this activity was found between the compounds (p = 0.0058).

H: Variable of the Kruskal-Wallis test decision; *: Meaningful; (1): (22E, 24S)-Stigmasta-5,22,25-trien-3β-ol; (2): 3β, 4β, 5β-tetrahydroxyflavone (luteolin); (3) Quercetin; (4) Kaempferol-7-O-β-D-glucoside; (5) aplothic acid; (6) β-sisotetranyl palmitate

Phytochemical analysis performed on the various extracts reveals the presence of numerous secondary metabolites such as phenolic compounds (tannins, flavonoids, coumarins...), saponins and terpenoids. These results are in agreement with the work carried out in 2014 by Kamga and his collaborators who isolated a new flavone with antioxidant activity and 3 saponins in this plant [10]. According to a study conducted in 2007 by Sokol-letowska [26], some of these secondary metabolites like phenolic compounds (flavonoids and tannins) have an important antioxidant activity due to the presence of many hydroxides that can react with free radicals [27]. The ability of compounds to trap free radicals depends on many parameters; the dose, structure, substituents and degree of polymerization of the molecule. Antiradical activity is very important because of the deleterious role of free radicals in the food and biological systems [27]. The DPPH radical method used in the present study is a common procedure in which the antioxidant activity of the sample studied is estimated by the degree of discoloration of the DPPH solution. This violet chromogen is easy to use, has high sensitivity, allows rapid analysis of the antioxidant activity of a large number of samples and gives reproducible results [27]. The qualitative test of the DPPH radical reduction method performed on the compounds showed numerous antiradical stains on the chromatographic profiles of compounds 1 and 2. While the quantitative evaluation of the free radical scavenging activity of DPPH has confirmed that the compounds have an antiradical activity. Nevertheless, the trapping capacity of these compounds remains lower compared to that of vitamin C (IC_{50}=7.87 mg/mL). According to Souri's classification [26], compound 4 has a high potential for antiradical activity (IC_{50}=20 mg/mL). Compounds 1 and 5 have a potential for moderate antiradical activity (20<IC_{50}<75 mg/mL), compounds 2 and 3 have a low potential (IC_{50}> 75 mg/mL). The antiradical activity of these compounds can be attributed to the presence of phenolic compounds found in phytochemical analysis because phenolic compounds have been shown to have the ability to yield hydrogen atoms generally associated with the presence of reducing agents [29]. The action of these antioxidants is

---

believed to be due to their ability to donate hydrogen or electron atoms derived mainly from the flavonoid ring a hydroxyl [30] and the study conducted by Kamba and collaborators in 2014 highlighted the presence of flavonoids in Albizia ferruginea extracts [10]. The antioxidant effect of flavonoids (FLOH) is attributed to their low redox potential which makes them thermodynamically capable of reducing free radicals (R•), by a transfer of hydrogen atom from the hydroxyl groups. This reaction gives rise to the aroxyl radical (FLO•) and to the stabilized radical molecule (RH), the FLO• will subsequently undergo a structural rearrangement allowing the redistribution of the single electron on the aromatic ring and the stabilization of aroxyl radicals [31]. The total antioxidant capacity of our compounds by the ferric reducing antioxidant power (FRAP) method has also been evaluated, ferric tripyridyltriazine (TPTZ) complex reduction to ferrous tripyridyltriazine by these compounds is probably due to the fact that they could reduce the activity, oxidizing free radicals by serving as electron donors. This property could be related to the phenolic compounds present in Albizia ferruginea extracts.

4. Conclusion

In this present work, we have investigated the antioxidant effects of compounds isolated from the roots of Albizia ferruginea belonging to the Fabaceae family, used in Cameroonian pharmacopoeia. The evaluation of the antioxidant activity shows that the isolated compounds of this plant and more particularly the roots of Albizia ferruginea would be a potential source of antioxidant substances. A study of the phytochemical composition of the extracts revealed the presence of numerous bioactive chemical compounds known for their biological activities. Our results showed that the tested crude extracts of this plant possess antioxidant activities in vitro. From this study, we can conclude that the extracts from CHCl3-MeOH (1:1) mixture of Albizia ferruginea bark roots and the isolated compounds possess interesting antioxidant properties.
