1. Introduction

In the past decades, nano-sized materials have attracted much attention owing to their interesting properties and potential application in many variety of fields. The properties of these materials are greatly affected by their size and shape [1, 2], which generate interest in the synthesis of semiconductor nanoparticles exhibiting different shapes, such as nanobelts and nanowires [3], nanospheres [4], nanoplates [5] and nanoflowers [6], among others.

ZnO is an n-type III-V semiconductor having direct band gap of 3.37 eV in addition with large excitation energy 60 meV and due to this it has eminent applications such as luminescence, optoelectronics, transparent electronics, ultraviolet (UV) light emitters, piezoelectric devices etc. [7, 8]. ZnO is also suitable for UV screening applications, because it has high chemical stability, low toxicity and is effective to inhibit pathogenic organisms [9]. In the previous studies, ZnO reveals the room temperature ferromagnetism (RTFM) when the metallic dopants like Al, Co, Mg and Mn etc., are successfully doped with ZnO NPs [10]. Sankara Reddy et al. have reported that ZnO and co-doped (Co, Ag) ZnO nanoparticles prepared by co-precipitation method without use of capping agent [11]. In the present work, LaCe co-doped ZnO NPs were synthesized by green method using G. sylvestre leaves extracts and their structural, optical and antibacterial properties have been investigated.

2. Experimental Methods

2.1 Green Synthesis of LaCe Co-Doped ZnO NPs

LaCe co-doped ZnO nanoparticles were prepared by green synthesis method using zinc nitrate, lanthanum nitrate and cerium nitrate as metal precursors (Zn, La and Ce respectively) and G. sylvestre leaves extract as reducing and capping agent. 15 g finely chopped G. sylvestre leaves were weighed, then 150 mL of double distilled water was added and boiled at 80 °C for 3 h. After the extract was cooled, the filter paper and the filtrate was collected in 250 mL Erlenmeyer flask. Thereafter, 0.297 M Zn(NO₃)₂.6H₂O, 0.002 M La(NO₃)₃.6H₂O and 0.001 M Ce(NO₃)₃.6H₂O solution was added into 150 mL of G. Sylvestre leaves extract and was stirred constantly at 80 °C for 6 hours. A dull yellow colour precipitate was obtained, further the precipitate was dried at 120 °C for 6 hours. The obtained LaCe co-doped ZnO powder was annealed at 700 °C for 6 hours.

2.2 Antibacterial Assay

The antibacterial activity of the LaCe co-doped NPs was tested against gram positive (Staphylococcus aureus and Streptococcus pneumoniae) and gram negative G. (Klebsiella pneumoniae, Shigella typhosa, Escherichia coli, Pseudomonas aeruginosa and Proteus vulgaris) bacterial strains using agar well diffusion method. Petri plates were prepared with 25 mL of sterile Muller Hinton agar (MHA, Himedia) and each bacterial pathogen was individually swabbed on MHA in separate plates. The antibacterial activity was tested at a concentration of 1.5 mg/mL with the required quantity of the NPs dispersed in dimethyl sulfoxide (DMSO). The zone of inhibition levels (mm) were measured after 24 h and before this step, it was incubated overnight at 37 °C. The standard antibiotic amoxicillin was used as the positive control.

2.3 Characterization Studies

The phase purity of the synthesized NPs were determined by X-ray diffractometer (Model: XPERT PRO PAN analytical). The morphological features of the sample were measured by Field emission scanning electron microscopy (Model: Carl Zeiss 55) with EDAX (ultras). The vibrational frequency was measured by Fourier transform infra-red spectroscopy (Perkin-Elmer). The absorption spectrum of the sample was measured on Perkin-Elmer (Lambda 35). The PL emission study of the sample was carried out using Horiba Jobin Yvon spectrophotometer (model: FLUOROMAX-4, 450W high pressure Xenon lamp as the excitation source, photomultiplier at a range 325-550 nm).

3. Results and Discussion

3.1 X-Ray Diffraction Studies

The X-ray diffraction peaks of LaCe co-doped ZnO NPs are shown in Fig. 1. The XRD peaks are located at angles (2θ) of 21.852, 34.515 and 36.302°, corresponding to the (100), (002) and (101) planes of the ZnO NPs, respectively. Similarly, other peaks found at angles (2θ) of 47.582, 56.683, 63.015, 66.48, 68.06, 69.25 and 77.60° correspond to (102), (110), (103), (105), (112), (104), (114) and (200) planes of ZnO NPs.
The absorption of water molecules can be indexed to the hexagonal wurtzite structure of ZnO (space group P63mc and CPDS 36-1451), while the existence of any crystalline secondary phase can be ruled out in the diffraction pattern [12]. The average crystalline size of the nanoparticles is calculated from X-ray line broadening using the Scherrer relation, \( D = 0.9 \lambda / \beta \cos \theta \), where \( D \) is the crystallite size, \( \lambda \) is the wavelength (1.5406 Å for CuK\( \alpha \)), \( \beta \) is the Bragg diffraction angle and \( \theta \) is the full width at half maximum (FWHM). The average crystallite size is calculated as 42 nm for LaCe co-doped ZnO NPs.

3.4 Fourier Transform Infrared (FTIR) Studies

The FT-IR spectra of LaCe co-doped ZnO NPs is shown in Fig. 4. The synthesized LaCe co-doped ZnO NPs was analyzed by FT-IR in the range from 400 to 4000 cm\(^{-1}\) at room temperature. The absorption peak appeared at 3410 cm\(^{-1}\) corresponds to the stretching vibration of the O–H band. This absorption peak is appeared due to the O–H stretching of surface absorption of water molecules [13]. The narrow intense H–O–H bending centered at 1648 cm\(^{-1}\). The medium intensity band 1385 cm\(^{-1}\) is attributed to C=O symmetric stretching. The weak band observed near 873 cm\(^{-1}\) is assigned to the metal-oxygen vibration frequency due to the changes in the micro structural features by the addition of La and Ce into Zn-O lattice [14]. The absorption bands of Zn–O stretching are exhibited in LaCe co-doped ZnO NPs are appeared at 464 cm\(^{-1}\).

3.5 UV-Vis Absorption Spectroscopy

The optical properties of LaCe co-doped ZnO NPs was investigated by UV-Vis absorption spectra, is shown in Fig. 5. From the absorption spectra, the absorption peak is found at 394 nm for LaCe co-doped ZnO NPs, which can be attributed to the photo excitation of electrons from valence band to conduction band [15].

3.6 Photoluminescence (PL) Studies

Fig. 6 shows the photoluminescence spectra of LaCe co-doped ZnO NPs using an excitation wavelength of 350 nm. In the case of LaCe co-doped ZnO NPs, the emission wavelengths are observed at 367, 386 and 395 nm, which correspond to the near-band emission (NBE) of LaCe co-doped ZnO NPs. The two violet emissions centered at 409 and 435 nm is ascribed to an electron transition from a shallow donor level of the natural zinc interstitials to the top level of the valence band [16]. The blue green emission observed at 482 nm is ascribed to the transition between the oxygen vacancy and interstitial oxygen [17]. Finally green emission observed at 520 nm, corresponds to the singly ionized oxygen vacancies [18, 19].

Fig. 6 PL emissions spectra of LaCe co-doped ZnO nanoparticles
Fig. 6 shows the photoluminescence spectra of LaCe co-doped ZnO NPs using an excitation wavelength of 350 nm. In the case of LaCe co-doped ZnO NPs, the emission wavelengths are observed at 367, 386, 395, 409, 435, 482 and 520 nm respectively. The UV emission peaks of lowest wavelength are observed at 367, 386 and 395 nm, which correspond to the near-band emission (NBE) of LaCe co-doped ZnO NPs. The two violet emissions centered at 409 and 435 nm is ascribed to an electron transition from a shallow donor level to the natural zinc interstitials to the top level of the valence band [16]. The blue green emission observed at 482 nm is ascribed to the transition between the oxygen vacancy and interstitial oxygen [17]. Finally green emission observed at 520 nm, corresponds to the singly ionized oxygen vacancies [18, 19].

3.7 Antibacterial Activity

The antibacterial activity was performed against a set of gram positive (G+) bacteria (S. aureus and S. pneumoniae) and gram negative (G-) (K. pneumoniae, E. coli, P. aeruginosa and P. vulgaris) bacteria by agar well diffusion methods using LaCe co-doped ZnO NPs are treated with concentration 1.5 mg/mL and it is shown in Fig. 7. The zone of inhibition (ZOI) of human pathogens is shown in Fig. 8. To compare the gram positive and gram negative bacteria, the observed inhibition zone was higher in gram positive bacteria. The Zone inhibition of bacterial cells may be due to distractions of cell membrane, is mainly due to the combination of various factors such as ROS and the release of Zn$^{2+}$, La$^{3+}$ and Ce$^{3+}$ bacteria losing the viability of cell division [20-23]. This leads to killing of bacteria.

Fig. 7 The progress of antibacterial activity of LaCe co-doped ZnO NPs

4. Conclusion

The LaCe co-doped ZnO NPs synthesized by green method using Gymnema sylvestre leaves extract. From the X-ray diffraction study confirmed that the prepared LaCe co-doped ZnO NPs were hexagonal wurtzite structure. From the FESEM image, the morphology of nanoparticles were found spherical in shape. The elemental composition was identified by EDAX spectra. Using the recorded FT-IR spectra, the various vibrational frequencies were assigned for the LaCe co-doped ZnO samples. The UV-Vis spectrum showed the absorption peak is found at 394 nm. PL spectra showed that doping materials altered the band emission, which is due to zinc vacancy, oxygen vacancy and surface defects. The antibacterial studies performed against a set of bacterial strains showed that the LaCe co-doped ZnO NPs possessed more antibacterial property.
